

CAPTIVE AND WILD BORN LEMURS

Hey stranger, during analyzing Lemurs data as a part of TidyTuesday challenge I noticed that Wild born animals are more 'happy' in terms of life expectancy and weight. But maybe there is a reason for that? Let's see!

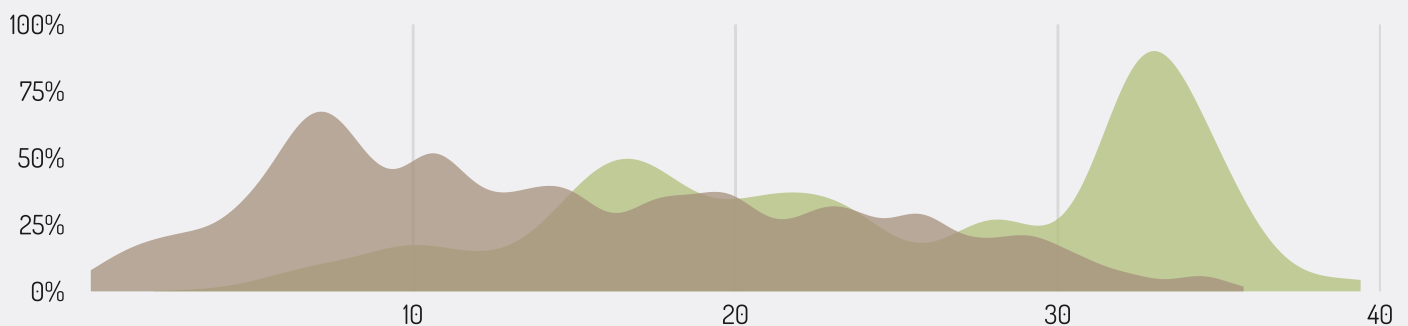

WEIGHT

We can see significant difference, the peaks are in different sides of the distribution. So maybe there is another variable influencing them?

AGE

Wild born lemurs representatives are in general older than Captive ones. We should stratify them

WEIGHT BY AGE GROUPS

Here we go: if analyze by age groups, median Weight is not that different. Note: we excluded groups with small number of observations
